

The Challenges Presented in Clinical Practice in Wales: *Safe Practice in DXA Scanning & Interpretation*

Angela Sims

*Senior Lecturer & DXA Service Lead,
Welsh Institute of Chiropractic,
University of South Wales*

Rebecca Pettit

*Principal Physicist & DXA Service Lead,
Cardiff & Vale UHB*

Today's Objectives

- How safe is our practice?
 - Clinical Governance
 - Training
 - Considerations for those who scan, create or interpret technical reports

The DXA Service at the Welsh Institute of Chiropractic (WIOC)

Calibration and Quality Control

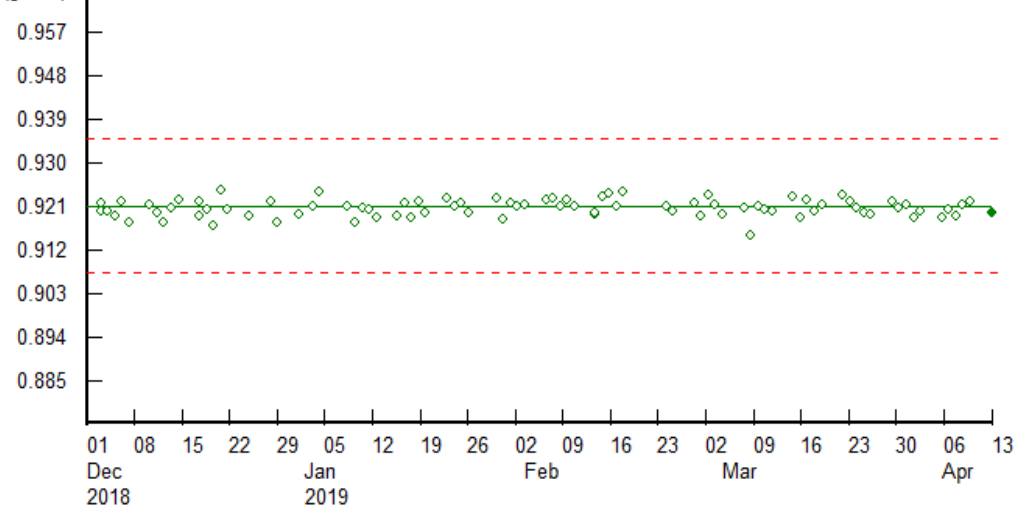

Quality Control
Spine Phantom

Quality Control Plot

BMD | BMC | AREA

BMD (g/cm²)

Quality Control
BMD Plot

Setup	Reference Values	Plot Statistics
a Lumbar Spine phantom #27030 System S/N: 200253	Limits: $\pm 1.5\%$ of mean Mean: 0.921 (g/cm ²) SD: 0.001 (g/cm ²)	Number of Points: 86 Mean: 0.920 (g/cm ²) SD: 0.002 (g/cm ²) CV: 0.187 %

Calibration and Quality Control

Figure 1: A gradual drift in a quality assurance history, which was a result of a slow oil leak.

Knapp et al. Osteoporosis Review 2014; Vol 22: No1: P 1-6

Image processing algorithms

$$\text{Bone Mineral Density (BMD) (g/cm}^2\text{)} = \frac{\text{Bone Mineral Content (BMC) (g)}}{\text{Area of bone (cm}^2\text{)}}$$

Edge detection image processing algorithm identifies bone using predetermined thresholds, and creating a “bone map” identifying the bone region in the acquired image.

DXA Operator can change the area of bone identified by manually adjusting the bone map.

Adjusting the bone map can either increase or decrease the area of bone identified and so can alter the BMD significantly.

Once the result is produced, it is not possible to tell what adjustments to the bone map have been made.

Manual Filling in of Bone Map on Hip Scan

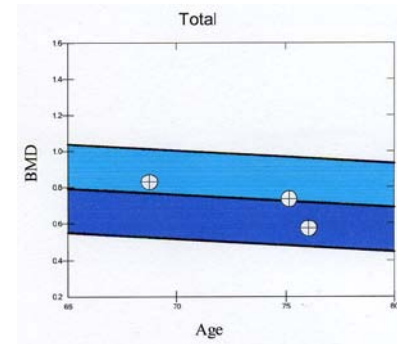

82-year-old woman on treatment. Scan comparison using automatic analysis failed to identify the bone in a large area of the hip. Operator painted in the missing bone total hip BMD appeared to decrease by 43% compared with the previous scan (spine BMD decreased by only 2%)

Automatic Filling in of Bone Map on Hip Scan

Upper border of the analysis box was raised, system software correctly identified the bone without the need for painting in. Total hip BMD was found to have decreased by only 1.5%.

Manual Filling in of Bone Map on Hip Scan

76-year-old female had a follow-up hip scan where automatic analysis using the scan comparison software failed to properly identify all the bone. When the missing bone was painted in total hip BMD appeared to decrease by 22% compared with the previous scan.

Bone Map determined using Low Density Software

In this case raising the upper border of the analysis box failed to solve the problem. When the scan was re-analysed without scan comparison the analysis defaulted to auto low density but now a large area of soft tissue above the femoral neck was included in the bone ROI. When this was painted out total hip BMD appeared to decrease by 8%.

L4	2.194	9.5	10.7

Clinical Conditions

In 1 year:
109% increase in Lumbar Spine BMD
72% increase in Total Hip BMD

Clinical Conditions

A. X-ray demonstrating a complete AFF in a 72-yr-old woman, who had been on risedronate for about 10 yr. B. She had routine DXA scan just before her presentation with AFF demonstrating a periosteal flare (arrow), which is delineated by the region of interest outline.

Ref Journal of Clinical Densitometry: Assessment & Management of Musculoskeletal Health, vol. 16, no. 4, 579e583, 2013 McKenna et al, Dublin

Clinical Conditions

2009 – Osteoporosis diagnosed.
Alendronic Acid commenced.

2013 –DXA scan identified suspicion of AFF on routine hip image confirmed on plain x-ray. Alendronic Acid stopped.
Daily subcutaneous Teriparatide injections started

2017 – Radiology report – previous stress fracture now healed.

Clinical Conditions

DXA image

Elderly ambulant patient.

“Yes I am in a bit of pain but that is normal at my age isn’t it?”

Precision of DXA Measurements

If measure the same patient twice consecutively, how similar are the results?

Manufacturer's quote precision values as:

Lumbar spine - 1-2 %

Proximal femur - 3-4 %

Whole body - 1-2 %

Precision varies due to

- machine
- operator
- patient

Precision of DXA Measurements

- Machine: Minimised by checking the QC phantom every day
- Operator: Minimised by training and taking care when positioning patients
- Patient has by far the greatest affect on precision, and so interpretation of changes in BMD need to take this into account

Patient: BMD change could be due to disease progression or response to treatment, but also significant weight gain/loss, inclusion of artefacts within region of interest, degenerative changes in the spine, aortic calcification, new vertebral fractures, worsening kyphosis or scoliosis

Sources of error

- The instrument
- The patient – avoidable and unavoidable
- The operator
- The report

The operator

- Patient preparation
- Patient positioning
- Image analysis

Patient Preparation

DXA Operator needs to make sure that the patient is properly prepared for the Investigation.

- Clothing – already discussed
- Determine whether recent examinations done (e.g. barium)
- Determine whether there are internal artefacts which can be avoided

DXA positioning – proximal femur

Internally rotate the leg 25° and abduct the leg 15° from midline

Positioning – Operator errors

ANGLE OF ROTATION	%CHANGE F NECK	%CHANGE TROCH.	% CHANGE WARD'S Δ
0°	+4.75	+0.55	+8.05
20° external	+6.06	+2.36	+0.78
40° external	+9.23	+0.69	+3.79
40° internal	+2.77	+0.69	+6.16

The effect of different degrees of rotation of the foot compared to a positioning angle of 20° internal rotation on BMD is shown.

Ref Palmer R. An evaluation of the limitations of the technique of Dual Energy Absorptiometry in the measurements of bone diseases. M Phil Thesis 1996. University of Glamorgan. UK.P110-113.

Positioning – Operator errors

- Neck Z score 3.2 with poor positioning reduced to 1.8 with better separation. Ischium still needs deleting

Sources of error

- The instrument
- The patient – avoidable and unavoidable
- The operator
- The report

The Report - Sources of error

- Failure to exclude artefacts
- Reference data
- T-Score and Z-score calculation

The Report - Reference data

Check patient date of birth, gender and ethnicity are correct in the patient demographics at the top of the report.

These are used to select the reference data for the calculation of Z and T-scores

The Report - Reference data

Z-score and T-score

$$\text{Z-score} = \frac{\text{Subject's BMD} - \text{Age matched mean}}{\text{Age matched SD}}$$

$$\text{T-score} = \frac{\text{Subject's BMD} - \text{Young adult mean}}{\text{Young adult SD}}$$

The Report - Reference data

White female

T-Score	Z-Score
-1.1	0.7

BMD=0.925 (g/cm²)

White male

T-Score	Z-Score
-1.5	-1.0

Black female

T-Score	Z-Score
-2.0	-0.7

Conclusions

- **Every part of the clinical procedure is open to error**
 - The instrument
 - The patient
 - The operator
 - The report
- **Artefacts can be a major cause of error if undetected**
- **Good communication between referrers, DXA department and reporting clinicians is vital**

Thank you for your attention.
